

Introduction to Quantum Statistics

- We had initiated the course with problems involving statistics.
- Now with our quantum mechanical background, we should have a relook at this issue.

- Let us imagine that we have a very large number of particles (say around Avogadro's number).
- Imagine a box which is of macroscopic dimensions.

- Assume that the energies are given by particle in a three dimension box as given below.
- In some cases we use slightly different boundary conditions.

$$E = \frac{\pi^2 \hbar^2}{2mL^2} (n_x^2 + n_y^2 + n_z^2)$$

$$\begin{aligned} E &= \frac{\pi^2 \hbar^2}{2mL^2} (n_x^2 + n_y^2 + n_z^2) \\ &= 3.76 \times 10^{-17} (n_x^2 + n_y^2 + n_z^2) \text{ eV} \\ &\quad \text{for an electron with } L=0.1\text{m} \\ \\ &= 2.04 \times 10^{-20} (n_x^2 + n_y^2 + n_z^2) \text{ eV} \\ &\quad \text{for a proton with } L=0.1\text{m} \end{aligned}$$

- The energy levels thus are fairly closely spaced almost forming continuum .
- However, the number of levels in a given energy range are finite though quite large.

Assumption

- Energy levels do not get disturbed when more than one particle is present. Ignore particle-particle interaction.

Problem

- If we give particles some energy, say in the form of heat, how these particles would occupy these states.
- Finally assume that the system to be at a finite temperature and that is the form of energy being given to them.

- Find the number of particles having a particular energy.
- This number depends on the characteristics of the particles that are going to occupy the states.

Type of Particles

1. **Classical Particles:** Distinguishable and do not obey Pauli Exclusion Principle.

2. **Quantum Particle 1 (Bosons):** Indistinguishable, Do not obey Pauli Exclusion Principle. These are particle with integral spins.

3. **Quantum Particle 2 (Fermions):** Indistinguishable, Obey Pauli Exclusion Principle. These are particle with non-integral spins.

Example

- Two particles.
- Three energy values 0 , E , $2E$.
- Four levels, degeneracy $1, 2, 1$
- Total energy $2E$.

A distribution would mean the number of particles having a particular energy, irrespective of the state corresponding to that energy.

First type

$2E \underline{A}$ $E \underline{\quad} \underline{\quad}$ $0 \underline{B}$	$2E \underline{B}$ $E \underline{\quad} \underline{\quad}$ $0 \underline{A}$		
$2E \underline{\quad}$ $E \underline{AB} \underline{\quad}$ $0 \underline{\quad}$	$2E \underline{\quad}$ $E \underline{\quad} \underline{AB}$ $0 \underline{\quad}$	$2E \underline{\quad}$ $E \underline{A} \underline{B}$ $0 \underline{\quad}$	$2E \underline{\quad}$ $E \underline{B} \underline{A}$ $0 \underline{\quad}$

Distribution

- Assume Equal a-priori probability.
- $(0,2,0)$ is twice probable than $(1,0,1)$.

$2E \underline{X}$ $E \underline{\quad} \underline{\quad}$ $0 \underline{X}$	$(0,2,0)$ is thrice probable than $(1,0,1)$
--	--

$2E \underline{\quad}$ $E \underline{XX} \underline{\quad}$ $0 \underline{\quad}$	$2E \underline{\quad}$ $E \underline{\quad} \underline{XX}$ $0 \underline{\quad}$	$2E \underline{\quad}$ $E \underline{X} \underline{X}$ $0 \underline{\quad}$
---	---	--

Third Type

$2E \underline{X}$ $E \underline{\quad} \underline{\quad}$ $0 \underline{X}$	$(0,2,0)$ is equally probable to $(1,0,1)$
--	---

$2E \underline{\quad}$ $E \underline{X} \underline{X}$ $0 \underline{\quad}$
--

General Problem

- Given a fixed amount of energy and a fixed number of particles.
- Given a set of energy levels E_i with degeneracies g_i .
- What is the most probable set of n_i ?
- Finally assume that the energy is given by heat at a temperature T .
